#### Input Layer

The input layer of a neural network is composed of artificial input neurons, and brings the initial data into the system for further processing by subsequent layers of artificial neurons.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ●

#### Input Layer

The input layer of a neural network is composed of artificial input neurons, and brings the initial data into the system for further processing by subsequent layers of artificial neurons.

#### Hidden Layer(s)

The hidden layers' job is to transform the inputs into something that the output layer can use.

#### Hidden Layer(s)

The hidden layers' job is to transform the inputs into something that the output layer can use.

#### Output Layer

The output layer the last layer of neurons that produces the outputs/decisions. The output layer neurons may be observed, given that they are the last "actor" nodes in the network.

# Multiclass learning

- One neuron can only separate 2 classes
- If we want to separate more than 2 classes we need more neurons in the outpu layer (one for each class)
- The class assosiated with the most active output neuron will be predicted
- The expected output (label) in this case is either the index of the class, or a one-hot vector (4 vs 00001000)

ション ふゆ く 山 マ チャット しょうくしゃ

# Multiclass learning

- As mentioned before, we have one output neuron for each class
- It would be good if output neurons could predict the  $p(c_i|x)$
- To achieve this, we need to change the activation function of the ouptut neurons

- It would be good if output neurons could predict the  $p(c_i|x)$
- To achieve this, we need to change the activation function of the ouptut neurons

#### Softmax activation

$$Softmax(z_i) = rac{e^{z_i}}{\sum_j (e^{z_j})}$$

Using this function, we can view the output vector as a probability vector.

### Cross-entropy loss function

- The MSE loss function is better suited for regression learning
- In case of classification, we need a different loss function that takes into account that we want to learn class probabilities

- In case of classification, we need a different loss function that takes into account that we want to learn class probabilities

Cross-entropy

$$CE(\theta, y) = -\frac{1}{N} \sum_{n \le N} \sum_{d \le D} y_{nd} \ln(o_{nd}),$$

where  $\theta$  holds the parameters of the network, y is the correct label vector, o is the output vector, N is the number of examples and D is the dimension of the output layer.

## The mathematical form of a neural network

- To understand the training algorithm, we need to formulate the neural network
- The whole network could be viewed as a function, applying matrix multiplications and the activation functions:
  - The parameters/weights of the *i*th layer will be denoted by  $W_i$

・ロト ・ 日 ・ エ ヨ ・ ト ・ 日 ・ うらつ

- The input for a hidden layer is either the input (X) or the output of a previous hidden layer
- *F<sub>i</sub>* denotes the activation function of the *i*th layer

- The whole network could be viewed as a function, applying matrix multiplications and the activation functions:
  - The parameters/weights of the *i*th layer will be denoted by  $W_i$
  - The input for a hidden layer is either the input (X) or the output of a previous hidden layer
  - F<sub>i</sub> denotes the activation function of the *i*th layer

Mathematical form of a NN with two hidden layer

 $NN(X) = F_2(W_2 * F_1(W_1 * F_0(W_0 * X)))$

# Backpropagation algorithm

- We can use the simple gradient descent algorithm to optimize the weights of the network
- Using the cross-entropy loss we can calculate the gradients of the output layer

▲ロト ▲圖ト ▲ヨト ▲ヨト ヨー のへで

• What about the hidden layers?

# Backpropagation algorithm

- We can use the simple gradient descent algorithm to optimize the weights of the network
- Using the cross-entropy loss we can calculate the gradients of the output layer
- What about the hidden layers?
- By derivating the NN function wrt. some parameters we can calculate the gradients of hidden neurons too (using the chain rule)

ション ふゆ く 山 マ チャット しょうくしゃ

# Backpropagation algorithm

- Calculate the output (feedforward phase)
- **2** Error of the output layer:  $o_i y_i$
- Backpropagation step: propagate the output error back layer by layer in the NN, each neurons distributes their error to their input neurons proportionately to the weights between them.
- Galculate the gradients, assuming sigmoid hidden activation:

ション ふゆ く 山 マ チャット しょうくしゃ

Opdate the parameters

## Stochastic backpropagation algorithm

- Sometimes we have to much data (memory is limited)
- Using only batches of data to update the network is a solution to this problem
- This means that we minimize different loss functions as the input data changes
- In practice this approach works quite well (even better than training on all data at once)
- Stochastic gradient descent (SGD) is the dominant method used to train deep learning models
- If the batchsize==1, then its called online learning, for small batchsizes (≤1000) its called minibatch training

# Input data

To help the optimizer it is usually necessery to rescale the input, especcialy if the features have different ranges

#### Normalization

Simply force all features into a predefined range ([0,1] or [-1,1])

# Input data

To help the optimizer it is usually necessery to rescale the input, especcialy if the features have different ranges

#### Normalization

Simply force all features into a predefined range ([0,1] or [-1,1])To achieve this we need to calculate the minimal and maximal value of each feature

#### Standardization

Outliers could hurt normalization, in this case we shift and rescale the features to have the same mean and deviation.

## The learning rate

Learning rate is a hyper-parameter that controls how much we are adjusting the weights of our network with respect the loss gradient.

## Tips and tricks

 Use a validation/development set to finetune the hyperparameters (learning rate, number of epochs)

ション ふゆ く 山 マ チャット しょうくしゃ

- Avoid overfitting and peeking
- More data is allways usefull
- Shuffling the data is helpfull for SGD
- Avoid large networks
